Chapter 1

The Role of Algorithms in Computing

1.1 Algorithms

1.1-1 Give a real-world example that requires sorting or a real-world example that requires computing a convex hull.

Solution. Any sort of problem involving organizing probably has sorting. For example, ordering a set of people by any quantitative characteristic (height, weight, test scores, age, their one mile run time, etc.).

Convex hulls are used widely in graphical simulations, for example to detect collisions. □

1.1-2 Other than speed, what other measures of efficiency might one use in a real-world setting?

Solution. Computer memory. Programmer time (time to implement algorithm). Energy efficiency. □

1.1-3 Select a data structure that you have seen previously, and discuss its strengths and limitations.

Solution. Linked lists have the advantage of being extendible up to the memory limit of your computer. Disadvantage of needing to traverse entire list to find an element (or determine if one isn't there) □

1.1-4 How are the shortest-path and traveling-salesman problems given above similar? How are they different?

Solution. Both are problems on weighted graphs involving attempting to minimize some subset of the graph (a path or a cycle). However, the shortest-path problem makes no requirement to end at the starting point, whereas the traveling-salesman problem does. This makes the shortest-path problem in P (solved by several algorithms, such as Dijkstra’s), and the traveling-salesman in NP-complete. \square

1.1-5 Come up with a real-world problem in which only the best solution will do. Then come up with one in which a solution that is “approximately” the best is good enough.

Solution. A problem where only the best solution will do is one that requires a fully correct solution, like needing a sorted list for a directory. One where an approximate solution, as discussed earlier in the chapter, would be solving traveling-salesman. \square

1.2 Algorithms as a technology

1.2-1 Give an example of an application that requires algorithmic content at the application level, and discuss the function of the algorithms involved.

Solution. Google Maps when giving directions to users uses algorithms to determine the quickest route, factoring in distance, tolls, predicted traffic at the time the user would be at a certain road, any reported accidents, etc. \square

1.2-2 Suppose we are comparing implementations of insertion sort and merge sort on the same machine. For inputs of size n , insertion sort runs in $8n^2$ steps, while merge sort runs in $64n \lg n$ steps. For which values of n does insertion sort beat merge sort?

Solution. This is asking for what values of n we have that $8n^2 \leq 64n \lg n$. We can simplify this to $2^{n/8} \leq n$. Plugging in values yields the largest valid integer value of n being 43. \square

1.2-3 What is the smallest value of n such that an algorithm whose running time is $100n^2$ runs faster than an algorithm whose running time is 2^n on the same machine?

Solution. This is asking what the smallest value of n such that $100n^2 \leq 2^n$ is, which is equivalent to when $n \leq \frac{2^{n/2}}{10}$. The value of n is 15. \square

1.3 Problems

1-1 For each function $f(n)$ and time t in the following table, determine the largest size n of a problem that can be solved in time t , assuming that the algorithm to solve the problem takes $f(n)$ microseconds.

Solution.

	1 second	1 minute	1 hour	1 day	1 month	1 year	1 century
$\lg n$	2^{1e6}	2^{6e7}	$2^{7.2e9}$	$2^{8.64e10}$	$2^{2.59e12}$	$2^{3.15e13}$	$2^{3.15e15}$
\sqrt{n}	$1e12$	$3.6e15$	$1.29e19$	$7.46e21$	$6.71e24$	$9.67e26$	$9.67e30$
n	$1e6$	$6e7$	$3.6e9$	$8.64e10$	$2.59e12$	$3.1104e13$	$3.11e15$
$n \lg n$	62746	2.80e6	1.33e8	2.75e9	7.18e10	7.8709e11	6.76e13
n^2	1000	7745	60000	293938	1609968	5577096	55770960
n^3	100	391	1532	4420	13736	98169	455661
2^n	19	25	31	36	41	44	51
$n!$	9	11	12	13	15	17	18

\square

Chapter 2

Getting Started

2.1 Insertion sort

2.1-1 Using Figure 2.2 as a model, illustrate the operation of INSERTION-SORT on the array $A = \langle 31, 41, 59, 26, 41, 58 \rangle$.

Solution. First pass: key set to 41. $A[1] = 31 < 41$, so the while loop breaks, and the second element stays put.

Second pass: key set to 59. Same steps as above.

Third pass: Key set to 26. $A[3] = 59 > 26$, so set $A[4] = 59$. $A[2] = 41 > 26$, so set $A[3] = 41$. $A[1] = 31 > 26$, so set $A[2] = 31$. Loop breaks, set $A[1] = 26$.

Fourth pass: Key set to 41. $A[4] = 59 > 41$, so set $A[5] = 59$. $A[3] = 41$, so the while loop breaks. Set $A[4] = 41$.

Final pass: Key set to 58. $A[5] = 59 > 58$, so set $A[6] = 59$. $A[4] = 41 < 58$, so the while loop breaks. Set $A[5] = 58$. The final sorted array is $\langle 26, 31, 41, 41, 58, 59 \rangle$. \square

2.1-2 Rewrite the INSERTION-SORT procedure to sort into nonincreasing instead of nondecreasing order.

Solution. Rewrite the algorithm as follows.

```

1  _____ REVERSE-INSERTION-SORT(A) _____
2  for j = 2 to A.length
3      key = A[j]
4      // Insert A[j] into the sorted sequence A[1..j-1].
5      i = j - 1
6      while i > 0 and A[i] < key // The only change
7          A[i + 1] = A[i]
8          i = i - 1
9      A[i + 1] = key

```

The implementation of this can be found in
code/<language>/chapter02/reverse_insertion_sort/. □

2.1-3 Consider the **searching problem**:

Input: A sequence of n numbers $A = \langle a_1, a_2, \dots, a_n \rangle$ and a value v .

Output: An index i such that $v = A[i]$ or the special value NIL if v does not appear in A .

Write pseudocode for **linear search**, which scans through the sequence, looking for v . Using a loop invariant, prove that your algorithm is correct. Make sure that your loop invariant fulfills the three necessary properties.

Solution. The algorithm is as follows.

```

1  _____ LINEAR-SEARCH(A, v) _____
2  for i = 1 to A.length
3      if A[i] == v
4          return i
5  return NIL

```

The loop invariant can be stated as follows: At the start of each iteration of the for loop, the subarray $A[1..i-1]$ does not contain the value v . We will show this invariant has the three necessary properties to prove the correctness of the algorithm. Prior to the first loop, the subarray $A[1..0]$ is an empty array, which clearly does not contain v . Suppose the invariant is true after loop i , that is, $A[1..i]$ does not contain v . Then on loop $i+1$, if $A[i+1] == v$, the algorithm will exit, returning $i+1$. If the algorithm does not exit, the loop iteration completes and thus $A[1..i+1]$ does not contain v . When the loop terminates without the algorithm prematurely returning, that means that v is not contained in $A[1..n]$, and thus NIL is returned. So the loop invariant fulfills the necessary properties to prove correctness of the algorithm. □

2.1-4 Consider the problem of adding two n -bit binary integers, stored in two n -element arrays A and B . The sum of the two integers should be stored in binary form in an $(n + 1)$ -element array C . State the problem formally and write pseudocode for adding the two integers.

Solution. Define the problems as follows:

Input: Two sequences A, B representing binary numbers, where the sequences are length n and contain only 0 or 1. The endianness of A, B should be defined, as it affects the algorithm to solve it. We will assume big-endian.

Output: A length $n + 1$ sequence representing the binary sum $A + B$.

Write the algorithm solving the problem as follows:

```

1  carry = 0
2  for i = A.length to 1
3      sum = A[i] + B[i] + carry // Binary addition
4      if sum % 10 == 1 // Sum either 01 or 11
5          S[i+1] = 1
6      if sum >= 10 // Sum either 10 or 11
7          carry = 1
8      else
9          carry = 0
10 S[0] = carry
11 return S

```

□

2.2 Analyzing algorithms

2.2-1 Express the function $n^3/1000 - 100n^2 - 100n + 3$ in terms of Θ -notation.

Solution. Considering the informal definition of Θ -notation in this chapter, we simply observe that the $n^3/1000$ term is the leading term and dominates for large n , and drop the coefficient, expressing the function as $\Theta(n^3)$. □

2.2-2 Consider sorting n numbers stored in array A by first finding the smallest element of A and exchanging it with the element in $A[1]$. Then find the second smallest element of A , and exchange it with $A[2]$. Continue in this

manner for the first $n - 1$ elements of A . Write pseudocode for this algorithm, which is known as **selection sort**. What loop invariant does this algorithm maintain? Why does it need to run for only the first $n - 1$ elements, rather than for all n elements? Give the best-case and worst-case running times of selection sort in Θ -notation.

Solution.

```

1  SELECTION-SORT(A)
2  for j = 1 to A.length - 1
3      current_min = stored_val = A[j]
4      stored_index = j
5      for i = j + 1 to A.length
6          if A[i] < current_min
7              current_min = A[i]
8              stored_index = i
9  A[j] = current_min
  A[stored_index] = stored_val

```

See `code/<language>/chapter02/selection_sort/` for implementation of this algorithm.

The loop invariant that the outer loop maintains is that the subarray $A[1..j]$ is sorted. Informally, this holds because the minimum element is selected to the first index, the second smallest element is selected to the second index, and so forth through the first j elements. The loop only needs to run for the first $n - 1$ elements because after $n - 1$ iterations, the largest element is necessarily in the final index, as the $n - i$ th largest elements are already all fixed to the i th indices. The best case runtime is $\Theta(n^2)$, since even with an input list that is already sorted, there is no way to early stop either for loop, as all elements need to be checked to confirm each candidate element is the current minimum. The worst case is equivalently $\Theta(n^2)$, as the same checks as in the best case are still performed, but the current minimum and stored index are updated on each increment of the i index (in Θ notation, this only adds a linear term which is already accounted for by the nested loop). \square

2.2-3 Consider linear search again (see Exercise 2.1-3). How many elements of the input sequence need to be checked on the average, assuming that the element being searched for is equally likely to be any element in the array? How about in the worst case? What are the average-case and worst-case running times of linear search in Θ notation? Justify your answers.

Solution. Assume the element to be checked is present in the array (otherwise no information is given on the ratio of present elements to non-present elements, and an average case is impossible to derive). The average case is equal to $\sum_i^n p(i) \cdot i$, where i is equal to each index. Since every index has equal probability to have the element, $p(i) = 1/n$. Thus, we have $\sum_i^n p(i) \cdot i = n(n+1)/(2n) = (n+1)/2$. In Θ notation, the average case is $\Theta(n)$ (strip away the coefficients / constants on the previous solution), and the worst case is $\Theta(n)$ (check n indices). \square

2.2-4 How can we modify almost any algorithm to have a good best-case running time?

Solution. Have an initial check to verify if the input is the solution (e.g., if the input array to a sorting algorithm is sorted). \square

2.3 Designing algorithms

2.3-1 Using Figure 2.4 as a model, illustrate the operation of merge sort on the array $A = \langle 3, 41, 52, 26, 38, 57, 9, 49 \rangle$.

Solution. The initial array of $\langle 3, 41, 52, 26, 38, 57, 9, 49 \rangle$ gets split up into arrays of length 1. Then, the arrays are paired off in order and merged together, to form $\langle 3, 41, 26, 52, 38, 57, 9, 49 \rangle$. Then, pairs are combined into 4 to give $\langle 3, 26, 41, 52, 9, 38, 49, 57 \rangle$. Then, the two sets of 4 are merged to get the final sorted array of $\langle 3, 9, 26, 38, 41, 49, 52, 57 \rangle$ \square

2.3-2 Rewrite the MERGE procedure so that it does not use sentinels, instead stopping once either array L or R has had all its elements copied back into A and then copying the remainder of the other array back into A .

Solution.

```

1  n_1 = q - p + 1
2  n_2 = r - q
3  let L[1..n_1] and R[1..n_2] be new arrays
4  for i = 1 to n_1
5      L[i] = A[p + i - 1]
6  for j = 1 to n_2
7      R[j] = A[q + j]
8  i = 1
9  j = 1
10 k = p
11 while i <= n_1 and j <= n_2
12     if L[i] <= R[j]
13         A[k] = L[i]
14         i = i + 1
15         k = k + 1
16     else
17         A[k] = R[j]
18         j = j + 1
19         k = k + 1

```

□

2.3-3 Use mathematical induction to show that when n is an exact power of 2, the solution of the recurrence

$$T(n) = \begin{cases} 2 & \text{if } n = 2, \\ 2T(n/2) + n & \text{if } n = 2^k, \text{ for } k > 1 \end{cases}$$

is $T(n) = n \lg n$.

Solution. Let $k = 1$. Then by definition of T , $T(2) = 2 = 2 \lg 2$.

Suppose the hypothesis is true for $k = m$. Let $k = m + 1$. We find that $T(2^{m+1}) = 2T(2^{m+1}/2) + 2^{m+1} = 2T(2^m) + 2^{m+1} = 2 \cdot 2^m \lg 2^m + 2^{m+1} = m \cdot 2^{m+1} + 2^{m+1} = (m + 1)2^{m+1} = 2^{m+1} \lg 2^{m+1}$. This proves the inductive hypothesis, and thus the result is true for all $k \in \mathbb{Z}^+$, or when n is a power of 2. □

2.3-4 We can express insertion sort as a recursive procedure as follows. In order to sort $A[1..n]$, we recursively sort $A[1..n-1]$ and then insert $A[n]$ into

the sorted array $A[1..n-1]$. Write a recurrence for the worst-case running time of this recursive version of insertion sort.

Solution.

$$T(n) = T(n-1) + (n-1)$$

This follows from considering the worst case of inserting $A[n]$ into sorted $A[1..n-1]$: needing to swap $A[n]$ with every index until it is at the first index. This yields $n-1$ swaps, in addition to all swaps to sort $A[1..n-1]$. Solving the recurrence is done by summing all integers from 1 to $n-1$, yielding $\Theta(n^2)$. \square

2.3-5 Referring back to the searching problem (see Exercise 2.1-3), observe that if the sequence A is sorted, we can check the midpoint of the sequence against v and eliminate half of the sequence from further consideration. The **binary search** algorithm repeats this procedure, halving the size of the remaining portion of the sequence each time. Write pseudocode, either iterative or recursive, for binary search. Argue that the worst-case running time of binary search is $\Theta(\lg n)$.

Solution.

```

1  BINARY-SEARCH(A, v, p, q)
2  if p == q and A[p] != v
3      return NIL
4  midpoint = floor((p + q) / 2)
5  if A[midpoint] == v
6      return midpoint
7  if A[midpoint] > v
8      return BINARY-SEARCH(A, v, p, midpoint)
9  return BINARY-SEARCH(A, v, midpoint, q)

```

The worst case is when the element is not in the list, in which case the array size must halve until it is one element large and the element is not the value to search for, returning NIL. Halving A this way to a size of one element takes $\lg n$ steps, so the procedure takes $\Theta(\lg n)$ time. \square

2.3-6 Observe that the **while** loop of lines 5-7 of the **INSERTION SORT** procedure in Section 2.1 uses a linear search to scan (backward) through the sorted subarray $A[1..j-1]$. Can we use a binary search (see Exercise 2.3-5)

instead to improve the overall worst-case running time of insertion sort to $\Theta(n \lg n)$?

Solution. It could be implemented, but it would not improve the running time to $\Theta(n \lg n)$. Once the index that $A[j]$ is to be inserted in is found, say index i , the elements of the subarray $A[i..j - 1]$ still need to be shifted into $A[i + 1..j]$. This will involve a nested loop that, in worst case, will still iterate over the entire subarray $A[1..j - 1]$, so the running time will still be $\Theta(n \lg n)$. \square

2.3-7* Describe a $\Theta(n \lg n)$ -time algorithm that, given a set S of n integers and another integer x , determines whether or not there exist two elements in S whose sum is exactly x .

Solution. Name this procedure PAIR-TO-SUM. The pseudocode for this procedure is given by the following.

	PAIR-TO-SUM(S, x)
1	$S = \text{MERGE-SORT}(S)$
2	$n = S.\text{size}$
3	for $i=1$ to n
4	$\text{value} = x - S[i]$
5	$\text{subarray} = \text{Union}(S[1..i-1], S[i+1..n])$
6	$j = \text{BINARY-SEARCH}(\text{subarray}, \text{value}, 1, n)$
7	if $j \neq \text{NIL}$
8	return i, j
9	return NIL

First, this procedure calls **MERGE-SORT**, which is $\Theta(n \lg n)$. Then, this procedure iterates over the n elements of S , binary searching for the unique element that would sum to x . Binary search is $\Theta(\lg n)$, and it is called n times in worst case, so this procedure is $\Theta(n \lg n)$. \square

2.4 Problems

2-1 Insertion sort on small arrays in merge sort

Although merge sort runs in $\Theta(n \lg n)$ worst-case time and insertion sort runs in $\Theta(n^2)$ worst-case time, the constant factors in insertion sort can

make it faster in practice for small problem sizes on many machines. Thus, it makes sense to **coarsen** the leaves of the recursion by using insertion sort within the merge sort when subproblems become sufficiently small. Consider a modification to merge sort in which n/k sublists of length k are sorted using insertion sort and then merged using the standard merging mechanism, where k is a value to be determined.

- (a) Show that insertion sort can sort the n/k sublists, each of length k , in $\Theta(nk)$ worst-case time.
- (b) Show how to merge sublists in $\Theta(n \lg(n/k))$ worst-case time.
- (c) Given that the modified algorithm runs in $\Theta(nk + n \lg(n/k))$ worst-case time, what is the largest value of k as a function of n for which the modified algorithm has the same running time as standard merge sort, in terms of Θ -notation?
- (d) How should we choose k in practice?

Solution.

- (a) There exist n/k sublists of length k . With insertion sort, each sublist takes $\Theta(k^2)$ time to sort. Since we do this $\Theta(k^2)$ operation n/k times, we multiply to find the worst time for insertion sort to sort all sublists is $\Theta(nk)$.
- (b) Perform the same steps as in normal merge sort, but since the branching tree of sublists is only $\lg(n/k)$ iterations deep instead of $\lg n$, merging the sublists takes $\Theta(n \lg(n/k))$ time.
- (c) The threshold is $k = \lg n$, at which point the first part of the sum will begin to dominate as k gets larger.
- (d) We can choose some constant value which isn't too large, for instance $k = 64$.

□

2-2 Correctness of bubblesort

Bubblesort is a popular, but inefficient, sorting algorithm. It works by repeatedly swapping adjacent elements that are out of order.

```

1  BUBBLESORT(A)
2  for i = 1 to A.length - 1
3      for j = A.length to i + 1
4          if A[j] < A[j - 1]
              exchange A[j] with A[j - 1]

```

- (a) Let A' denote the output of `BUBBLESORT(A)`. To prove that `BUBBLESORT` is correct, we need to prove that it terminates and that

$$A'[1] \leq A'[2] \leq \cdots \leq A'[n], \quad (2.1)$$

where $n = A.length$. In order to show that `BUBBLESORT` actually sorts, what else do we need to prove?

The next two parts will prove inequality (2.1).

- (b) State precisely a loop invariant for the **for** loop in lines 2-4, and prove that this loop invariant holds. Your proof should use the structure of the loop invariant proof presented in this chapter.
- (c) Using the termination condition of the loop invariant proved in part (b), state a loop invariant for the **for** loop in lines 1-4 that will allow you to prove inequality (2.1). Your proof should use the structure of the loop invariant proof presented in this chapter.
- (d) What is the worst-case running time of bubblesort? How does it compare to the running time of insertion sort?

Solution.

□

2-3 Correctness of Horner's rule

The following code fragment implements Horner's rule for evaluating a polynomial

$$\begin{aligned}
 P(x) &= \sum_{k=0}^n a_k x^k \\
 &= a_0 + x(a_1 + x(a_2 + \cdots + x(a_{n-1} + xa_n) \cdots)),
 \end{aligned}$$

Given the coefficients a_0, a_1, \dots, a_n and a value for x :

```

1  y = 0
2  for i = n downto 0
3      y = a_i + x * y

```

- (a) In terms of Θ -notation, what is the running time of this code fragment for Horner's rule?
- (b) Write pseudocode to implement the naive polynomial-evaluation algorithm that computes each term of the polynomial from scratch. What is the running time of this algorithm? How does it compare to Horner's rule?
- (c) Consider the following loop invariant: At the start of each iteration of the **for** loop of lines 2-3,

$$y = \sum_{k=0}^{n-(i+1)} a_{k+i+1} x^k.$$

Interpret a summation with no terms as equaling 0. Following the structure of the loop invariant proof presented in this chapter, use this loop invariant to show that, at termination, $y = \sum_{k=0}^n a_k x^k$.

- (d) Conclude by arguing that the given code fragment correctly evaluates a polynomial characterized by the coefficients a_0, a_1, \dots, a_n .

Solution.

□

2-4 Inversions

Let $A[1..n]$ be an array of n distinct numbers. If $i < j$ and $A[i] > A[j]$, then the pair (i, j) is called an **inversion** of A .

- (a) List the five inversions of the array $\langle 2, 3, 8, 6, 1 \rangle$.
- (b) What array with elements from the set $\{1, 2, \dots, n\}$ has the most inversions? How many does it have?
- (c) What is the relationship between the running time of insertion sort and the number of inversions in the input array? Justify your answer.

- (d) Give an algorithm that determines the number of inversions in any permutation on n elements in $\Theta(n \lg n)$ worst-case time. (*Hint:* Modify merge sort.)

Solution.

- (a) The inversions are $(1, 5), (2, 5), (3, 5), (4, 5), (3, 4)$.
- (b) The array with the most inversions is the reverse sorted array: $[n, n - 1, \dots, 2, 1]$. It has $n - 1$ inversions for the first element, $n - 2$ for the second, and so forth, for a total of $1 + 2 + \dots + n - 1 = n(n - 1)/2$.
- (c) Insertion sort works by iterating through each element in the array, undoing every inversion an element has with elements appearing prior to it in the array. Thus, if $I(A)$ is a formula for the number of inversions in an array, the running time of insertion sort is equal to $I(A) + \Theta(n)$, where the code to maintain the state of the procedure is $\Theta(n)$.
- (d) Take merge sort, and add to a counter for every element added to the array from the right array before all elements from the left are depleted. Return this count for every subprocess, and add these counts together to get the total number of inversions.

□

Chapter 3

Growth of Functions

3.1 Asymptotic notation

3.1-1 Let $f(n)$ and $g(n)$ be asymptotically nonnegative functions. Using the basic definition of Θ -notation, prove that $\max(f(n), g(n)) = \Theta(f(n) + g(n))$.

Solution. Recall that

$$\max(f(n), g(n)) = \frac{f(n) + g(n) + |f(n) - g(n)|}{2}$$

and that

$$0 \leq |f(n) - g(n)| \leq |f(n)| + |g(n)|.$$

Substituting these in to the definition of $\Theta(f(n) + g(n))$ yields

$$\begin{aligned} 0 \leq c_1(f(n) + g(n)) \leq \max(f(n), g(n)) &\leq c_2(f(n) + g(n)), \\ 2c_1(f(n) + g(n)) \leq f(n) + g(n) + |f(n) - g(n)| &\leq 2c_2(f(n) + g(n)). \end{aligned}$$

Setting $c_1 = 1/2$ and $c_2 = 1$ yields the desired inequality, as follows by the inequalities with $|f(n) - g(n)|$ above. \square

3.1-2

Show that for any real constants a and b , where $b > 0$,

$$(n + a)^b = \Theta(n^b).$$

Solution. For $(n + a)^b = \Theta(n^b)$, we need to show that there exist $c_1, c_2, n_0 > 0$ such that $0 \leq c_1 n^b \leq (n + a)^b \leq c_2 n^b$. We can manipulate this inequality

to yield

$$\begin{aligned}
 c_1 n^b &\leq (n+a)^b && \leq c_2 n^b, \\
 c_1 &\leq \frac{(n+a)^b}{n^b} && \leq c_2, \\
 c_1 &\leq \left(\frac{n+a}{n}\right)^b && \leq c_2, \\
 \sqrt[b]{c_1} &\leq 1 + \frac{a}{n} && \leq \sqrt[b]{c_2}, \\
 \sqrt[b]{c_1} - 1 &\leq \frac{a}{n} && \leq \sqrt[b]{c_2} - 1.
 \end{aligned}$$

If $a \geq 0$, then setting $c_1 = 1$, $c_2 = (a+1)^b$, for $n_0 = 1$, the inequality is satisfied. If $a < 0$, then for $c_1 = \frac{1}{2^b}$, $c_2 = 1$, and $n_0 > -2a$, the inequality is satisfied. \square

3.1-3 Explain why the statement, “The running time of the algorithm A is at least $O(n^2)$ ” is meaningless.

Solution. O -notation provides an asymptotic upper bound for a function, that is, that $f(n) \leq cg(n)$ for all $n \geq N_0$. To say that a function is “at least $O(n^2)$ ” would imply that a function is greater than some upper bound in $O(n^2)$, which gives no information. For example, it can be greater than a constant $g(n) = c \in O(n^2)$. (the wording for this question being so confusing is why I hate the abuse of notation saying a function “is” $O(f(n))$ rather than a function is “in” $O(f(n))$... like what does it mean for the running time to be at least a set? Or maybe that’s the point.) \square

3.1-4 Is $2^{n+1} = O(2^n)$? Is $2^{2n} = O(2^n)$?

Solution. Since $2^{n+1} = 2 \cdot 2^n$, we have $2^{n+1} = O(2^n)$ by choice of $c = 2$, $n_0 = 1$.

Since $2^{2n} = 2^n \cdot 2^n$, for $2^{2n} = O(2^n)$ we would need some constant c such that $2^{2n} \leq c \cdot 2^n \implies 2^n \leq c$, which is not true for any constant choice of c for all $n \geq n_0$ for any n_0 . Thus $2^{2n} \neq O(2^n)$. \square

3.1-5 Prove Theorem 3.1.

Proof. Suppose $f(n) = \Theta(g(n))$. Then there exist c_1, c_2, n_0 such that $0 \leq c_1 g(n) \leq f(n) \leq c_2 g(n)$ for all $n \geq n_0$. It is then clear that for $c = c_1, n_0 = n_0$, we have $0 \leq f(n) \leq c g(n)$, so $f(n) = O(g(n))$ and for $c = c_2, n_0 = n_0$, we have $0 \leq c g(n) \leq f(n)$, so $f(n) = \Omega(g(n))$.

Suppose $f(n) = O(g(n))$ and $f(n) = \Omega(g(n))$. Let (c_O, n_O) be a choice of c, n_0 satisfying $f(n) = O(g(n))$ and let (c_Ω, n_Ω) be a choice of c, n_0 satisfying $f(n) = \Omega(g(n))$. Choose $n_0 = \max\{n_O, n_\Omega\}$, $c_1 = C_\Omega$, and $c_2 = C_O$. For these choices of constants we have that $0 \leq c_1 g(n) \leq f(n) \leq c_2 g(n)$ for all $n \geq n_0$, and thus $f(n) = \Theta(g(n))$. \square

3.1-6 Prove that the running time of an algorithm is $\Theta(g(n))$ if and only if its worst-case running time is $O(g(n))$ and its best-case running time is $\Omega(g(n))$.

Proof. Suppose the running time $f(n)$ of an algorithm is $\Theta(g(n))$. Then $f(n) \in O(g(n))$ and $f(n) \in \Omega(g(n))$. By the former, we have that $0 \leq f(n) \leq c g(n)$, so the runtime can't get any worse than $O(g(n))$, and by the latter we have that $0 \leq c g(n) \leq f(n)$, so the runtime can't get any better than $\Omega(g(n))$.

Suppose the running time of an algorithm $f(n)$ has worst-case running time $O(g(n))$ and best-case running time $\Omega(g(n))$. By the former, we have $f(n) \leq c g(n)$ (runtime can't get any worse than $g(n)$), and by the latter we have $c' g(n) \leq f(n)$ (runtime can't get any better than $g(n)$). Together this clearly yields that $f(n) = \Theta(g(n))$. \square

3.1-7 Prove that $o(g(n)) \cap \omega(g(n))$ is the empty set.

Proof. Suppose $f \in o(g(n)) \cap \omega(g(n))$. Since $f \in o(g(n))$, for any $c > 0$ there exists n_0 such that $0 \leq f(n) < c g(n)$. Since $f \in \omega(g(n))$, for any $c > 0$ there exists n'_0 such that $0 \leq c g(n) < f(n)$. Take $N = \max\{n_0, n'_0\}$. Then for all $n \geq N$, we have $0 \leq c g(n) < f(n) < c g(n)$, a contradiction. \square

3.1-8 We can extend our notation to the case of two parameters n and m that can go to infinity independently at different rates. For a given function

$g(n, m)$, we denote by $O(g(n, m))$ the set of functions

$$O(g(n, m)) = \{f(n, m) : \text{there exist positive constants } c, n_0, \text{ and } m_0 \\ \text{such that } 0 \leq f(n, m) \leq cg(n, m) \\ \text{for all } n \geq n_0 \text{ or } m \geq m_0\}.$$

Give corresponding definitions for $\Omega(g(n, m))$ and $\Theta(g(n, m))$.

Solution.

$$\Omega(g(n, m)) = \{f(n, m) : \text{there exist positive constants } c, n_0, \text{ and } m_0 \\ \text{such that } 0 \leq cg(n, m) \leq f(n, m) \\ \text{for all } n \geq n_0 \text{ or } m \geq m_0\}.$$

$$\Theta(g(n, m)) = \{f(n, m) : \text{there exist positive constants } c_1, c_2, n_0, \text{ and } m_0 \\ \text{such that } 0 \leq c_1g(n, m) \leq f(n, m) \leq c_2g(n, m) \\ \text{for all } n \geq n_0 \text{ or } m \geq m_0\}.$$

□

3.2 Standard notations and common functions

3.2-1 Show that if $f(n)$ and $g(n)$ are monotonically increasing functions, then so are the functions $f(n) + g(n)$ and $f(g(n))$, and if $f(n)$ and $g(n)$ are in addition nonnegative, then $f(n) \cdot g(n)$ is monotonically increasing.

Solution. Suppose f, g are monotonically increasing, so $m \leq n$ implies $f(m) \leq f(n)$ and $g(m) \leq g(n)$. Then we have that $f(m) + g(m) \leq f(n) + g(m) \leq f(n) + g(n)$, so $f + g$ is monotonically increasing. In addition, since $m \leq n$ implies $g(m) \leq g(n)$, plugging this in to f (which is monotonically increasing) yields $f(g(m)) \leq f(g(n))$, so $f \circ g$ is monotonically increasing. □

3.2-2 Prove equation (3.16)

Proof.

$$\begin{aligned}
 a^{\log_b c} &= b^{(\log_b a^{\log_b c})} \\
 &= b^{(\log_b a \log_b c)} \\
 &= b^{(\log_b c^{\log_b a})} \\
 &= c^{\log_b a}.
 \end{aligned}$$

□

3.2-3 Prove equation (3.19). Also prove that $n! = \omega(2^n)$ and $n! = o(n^n)$.

Proof. By Stirling's approximation, we have

$$\begin{aligned}
 \lg(n!) &= \lg \left(\sqrt{2\pi n} \left(\frac{n}{e} \right)^n \left(1 + \Theta \left(\frac{1}{n} \right) \right) \right) \\
 &= \lg(\sqrt{2\pi n}) + n(\lg n - \lg e) + \lg \left(1 + \Theta \left(\frac{1}{n} \right) \right) \\
 &= \Theta(n \lg n).
 \end{aligned}$$

For $n! = \omega(2^n)$, let $c > 0$ and let $n_0 = \max\{2 \cdot \lceil c \rceil, 4\}$. Observe that for all $n \geq n_0$, $n! = n \cdot (n-1) \cdots n_0 \cdots 2 \cdot 1 = 2(n \cdot (n-1) \cdots (n_0/2) \cdots 2 \cdot 1) > 2(2 \cdot 2 \cdots 2 \cdot 1) = 2^n$.

For $n! = o(n^n)$, let $c > 0$ and let $n_0 = \max\{2 \cdot \lceil c \rceil, 4\}$. Observe that for all $n \geq n_0$, $n! = n \cdot (n-1) \cdots n_0 \cdots 2 \cdot 1 < c(n \cdots c \cdots 2 \cdot 1) < c \cdot n^n$, thus $n! = o(n^n)$. □

3.2-4 * Is the function $\lceil \lg n \rceil!$ polynomially bounded? Is the function $\lceil \lg \lg n \rceil!$ polynomially bounded?

Solution.

□

3.2-5 * Which is asymptotically larger: $\lg(\lg^* n)$ or $\lg^*(\lg n)$

Solution.

□

3.2-6 Show that the golden ratio ϕ and its conjugate $\hat{\phi}$ both satisfy the equation $x^2 = x + 1$.

Solution. Given $\phi = \frac{1+\sqrt{5}}{2}$, we have $\phi^2 = \frac{3}{2} + \frac{\sqrt{5}}{2} = \frac{1+\sqrt{5}}{2} + 1$. Thus, ϕ satisfies $x^2 = x + 1$.

Given $\hat{\phi} = \frac{1-\sqrt{5}}{2}$, we have $\hat{\phi}^2 = \frac{3}{2} - \frac{\sqrt{5}}{2} = 1 + \frac{1-\sqrt{5}}{2}$. Thus, $\hat{\phi}$ satisfies $x^2 = x + 1$. \square

3.2-7 Prove by induction that the i th Fibonacci number satisfies the equality

$$F_i = \frac{\phi^i - \hat{\phi}^i}{\sqrt{5}},$$

where ϕ is the golden ratio and $\hat{\phi}$ is its conjugate.

Proof. For $n = 0$, we have $F_0 = \frac{1-1}{\sqrt{5}} = 0$, as desired. For $n = 1$, we have $F_1 = \frac{\phi - \hat{\phi}}{\sqrt{5}} = \frac{\frac{1+\sqrt{5}}{2} - \frac{1-\sqrt{5}}{2}}{\sqrt{5}} = 1$, as desired.

Suppose the equality is true for all $n \leq N$. Let $n = N + 1$. Notice that by question 3.2-6, ϕ and $\hat{\phi}$ satisfy $x^{N+1} = x^N + x^{N-1}$. Then we have

$$\begin{aligned} F_{N+1} &= F_N + F_{N-1} \\ &= \frac{\phi^N - \hat{\phi}^N}{\sqrt{5}} + \frac{\phi^{N-1} - \hat{\phi}^{N-1}}{\sqrt{5}} \\ &= \frac{\phi^N + \phi^{N-1} - (\hat{\phi}^N + \hat{\phi}^{N-1})}{\sqrt{5}} \\ &= \frac{\phi^{N+1} - \hat{\phi}^{N+1}}{\sqrt{5}}. \end{aligned}$$

Thus, by induction, $F_i = \frac{\phi^i - \hat{\phi}^i}{\sqrt{5}}$ as desired. \square

3.2-8 Show that $k \ln k = \Theta(n)$ implies $k = \Theta(n/\ln n)$.

Solution. By the symmetry property of asymptotics, we have $f(n) = \Theta(g(n))$ if and only if $g(n) = \Theta(f(n))$. Since $k \ln k = \Theta(n)$, we can use the symmetry property to obtain $n = \Theta(k \ln k)$. Taking the logarithm of both sides, we obtain $\ln n = \Theta(\ln k + \ln \ln k) = \Theta(\ln k)$. Dividing $n = \Theta(k \ln k)$ by this yields $\frac{n}{\ln n} = \Theta(k)$. Using the symmetry property again yields $k = \Theta(\frac{n}{\ln n})$. \square

3.3 Problems

3-1 Asymptotic behavior of polynomials

Let

$$p(n) = \sum_{i=0}^d a_i n^i,$$

where $a_d > 0$, be a degree- d polynomial in n , and let k be a constant. Use the definitions of the asymptotic notations to prove the following properties

- (a) If $k \geq d$, then $p(n) = O(n^k)$.
- (b) If $k \leq d$, then $p(n) = \Omega(n^k)$.
- (c) If $k = d$, then $p(n) = \Theta(n^k)$.
- (d) If $k > d$, then $p(n) = o(n^k)$.
- (e) If $k < d$, then $p(n) = \omega(n^k)$.

Solution.

□

3-2 Relative asymptotic growths

Indicate, for each pair of expressions (A, B) in the table below, whether A is O, o, Ω, ω or Θ of B . Assume that $k \geq 1$, $\varepsilon > 0$, and $c > 1$ are constants. Your answer should be in the form of the table with “yes” or “no” written in each box.

A	B	O	o	Ω	ω	Θ
$\lg^k n$	n^ε	Yes	Yes	No	No	No
n^k	c^n	Yes	Yes	No	No	No
\sqrt{n}	$n^{\sin n}$	No	No	No	No	No
2^n	$2^{n/2}$	No	No	Yes	Yes	No
$n^{\lg c}$	$c^{\lg n}$	Yes	No	Yes	No	Yes
$\lg(n!)$	$\lg(n^n)$	Yes	No	Yes	No	Yes

□

3-3 Ordering by asymptotic growth rates

- (a) Rank the following functions by order of growth; that is, find an arrangement g_1, g_2, \dots, g_{30} of the functions satisfying $g_1 = \Omega(g_2)$, $g_2 = \Omega(g_3), \dots, g_{29} = \Theta(g_{30})$. Partition your list into equivalence classes such that functions $f(n)$ and $g(n)$ are in the same class iff $f(n) = \Theta(g(n))$.

$\lg(\lg^* n)$	$2^{\lg^* n}$	$(\sqrt{2})^{\lg n}$	n^2	$n!$	$(\lg n)!$
$(\frac{3}{2})^n$	n^3	$\lg^2 n$	$\lg(n!)$	2^{2^n}	$n^{1/\lg n}$
$\ln \ln n$	$\lg^* n$	$n \cdot 2^n$	$n^{\lg \lg n}$	$\ln n$	1
$2^{\lg n}$	$(\lg n)^{\lg n}$	e^n	$4^{\lg n}$	$(n+1)!$	$\sqrt{\lg n}$
$\lg^*(\lg n)$	$2^{\sqrt{2 \lg n}}$	n	2^n	$n \lg n$	$2^{2^{n+1}}$

- (b) Give an example of a single nonnegative function $f(n)$ such that for all functions $g_i(n)$ in part (a), $f(n)$ is neither $O(g_i(n))$ nor $\Omega(g_i(n))$.

Solution.

□

3-4 Asymptotic notation properties

Let $f(n)$ and $g(n)$ be asymptotically positive functions. Prove or disprove each of the following conjectures.

- (a) $f(n) = O(g(n))$ implies $g(n) = O(f(n))$.
- (b) $f(n) + g(n) = \Theta(\min(f(n), g(n)))$.
- (c) $f(n) = O(g(n))$ implies $\lg(f(n)) = O(\lg(g(n)))$, where $\lg(g(n)) \geq 1$ and $f(n) \geq 1$ for all sufficiently large n .
- (d) $f(n) = O(g(n))$ implies $2^{f(n)} = O(2^{g(n)})$.
- (e) $f(n) = O((f(n))^2)$.
- (f) $f(n) = O(g(n))$ implies $g(n) = \Omega(f(n))$.
- (g) $f(n) = \Theta(f(n/2))$
- (h) $f(n) + o(f(n)) = \Theta(f(n))$.

Solution.

- (a) False. Let $f(n) = n$ and $g(n) = n^2$.

(b) False. Let $f(n) = n$ and $g(n) = n^2$.

(c) alkfj

(d) alkfj

(e) False. Let $f(n) = \frac{1}{n}$.

□

3-5 Variations on O and Ω

Some authors define Ω in a slightly different way than we do; let's use Ω_∞ (read “omega infinity”) for this alternative definition. We say that $f(n) = \Omega_\infty(g(n))$ if there exists a positive constant c such that $f(n) \geq cg(n) \geq 0$ for infinitely many positive integers n .

- (a) Show that for any two functions $f(n)$ and $g(n)$ that are asymptotically nonnegative, either $f(n) = O(g(n))$ or $f(n) = \Omega_\infty(g(n))$ or both, whereas this is not true if we use Ω in place of Ω_∞ .
- (b) Describe the potential advantages and disadvantages of using Ω_∞ instead of Ω to characterize the running times of programs.

Some authors also define O in a slightly different manner; let's use O' for the alternative definition. We say that $f(n) = O'(g(n))$ iff $|f(n)| = O(g(n))$.

- (c) What happens to each direction of the “if and only if” in Theorem 3.1 if we substitute O' for O but still use Ω ?

Some authors define \tilde{O} (read “soft-oh”) to mean O with logarithmic factors ignored:

$$\tilde{O}(g(n)) = \{f(n) : \text{there exist positive constants } c, k, \text{ and } n_0 \text{ such that} \\ 0 \leq f(n) \leq cg(n) \lg^k(n) \text{ for all } n \geq n_0\}.$$

- (d) Define $\tilde{\Omega}$ and $\tilde{\Theta}$ in a similar manner. Prove the corresponding analog to Theorem 3.1.

Solution.

□

3-6 Iterated functions

We can apply the iteration operator $*$ used in the \lg^* function to any monotonically increasing function $f(n)$ over the reals. For a given constant $c \in \mathbb{R}$, we define the iterated function f_c^* by

$$f_c^*(n) = \min\{i \geq 0 : f^{(i)}(n) \leq c\},$$

which need not be well defined in all cases. In other words, the quantity $f_c^*(n)$ is the number of iterated applications of the function f required to reduce its argument down to c or less.

For each of the following functions $f(n)$ and constants c , give as tight of a bound as possible on $f_c^*(n)$.

(a) $f(n) = n - 1, c = 0.$

(b) $f(n) = \lg n, c = 1.$

(c) $f(n) = n/2, c = 1.$

(d) $f(n) = n/2, c = 2.$

(e) $f(n) = \sqrt{n}, c = 2.$

(f) $f(n) = \sqrt{n}, c = 1.$

(g) $f(n) = n^{1/3}, c = 2.$

(h) $f(n) = n/\lg n, n = 2.$

Solution.

□

Chapter 4

Divide-and-Conquer

4.1 The maximum-subarray problem

4.1-1 What does FIND-MAXIMUM-SUBARRAY return when all elements of A are negative?

Solution.

□

4.1-2 Write pseudocode for the brute-force method of solving the maximum-subarray problem. Your procedure should run in $\Theta(n^2)$ time.

Solution.

□

4.1-3 Implement both the brute-force and recursive algorithms for the maximum-subarray problem on your own computer. What problem size n_0 gives the crossover point at which the recursive algorithm beats the brute-force algorithm? Then, change the base case of the recursive algorithm to use the brute-force algorithm whenever the problem size is less than n_0 . Does that change the crossover point?

Solution.

□

4.1-4 Suppose we change the definition of the maximum-subarray problem to allow the result to be an empty subarray, where the sum of the values of an empty subarray is 0. How would you change any of the algorithms that do now allow empty subarrays to permit an empty subarray to be the result?

Solution.

□

4.1-5 Use the following ideas to develop a nonrecursive, linear-time algorithm for the maximum-subarray problem. Start at the left end of the array, and progress toward the right, keeping track of the maximum subarray seen so far. Knowing a maximum subarray of $A[1..j]$, extend the answer to find a maximum subarray ending at index $j + 1$ by using the following observation: a maximum subarray of $A[1..j + 1]$ is either a maximum subarray of $A[1..j]$ or a subarray $A[i..j + 1]$, for some $1 \leq i \leq j + 1$. Determine a maximum subarray of the form $A[i..j + 1]$ in constant time based on knowing a maximum subarray ending at index j .

Solution.

□
